Practical1

Aim:-DesigningDatabaseUsingERModelling

Que1CreatedatabasedesignforHospitalManagementSystemusingER Modelling

The patient, physician, department, room, and appointment are the entities that make up the hospital administration system.
The following is a relationship between these entities areas:

An appointment is for one patient and one doctor. A patient may have one or more appointments. A doctor may schedule many appointments with various patients.
One department is assigned to a doctor.
A department may employ several physicians.
One patient can be assigned to one room, and one or more patients can be housed in a room.
A doctor is in charge of each room, however they can oversee more than one. These relationships allow us to develop the subsequent ER model:

1.Entities:
- Patient with attributes (Name, Age, Room Number, and Patient ID).
- Physician with the following attributes: DepartmentID, Name, Specialty, DoctorID.
- Department including features like DepartmentName, DepartmentID.
  Room has the following attributes: bed count, supervising doctor ID, room number.
- Appointment with the following attributes: PatientID, DoctorID, Date, Time, Appointment ID.

2. Relationships:
A patient's relationship with an appointment is symbolized by a "has" relationship.
A doctor-patient connection is based on a "conducts" relationship.
A department and a doctor are associated, represented by a "assignedto" relationship.
Multiple doctors are associated with a department through the "employs" relationship.
A patient and a room are connected through a "assignedto" relationship.
A room can have a relationship with numerous patients, represented by a "houses" relationship.
A room has a relationship with a doctor, which is represented by a "supervisedby" relationship. An diagram representing things as boxes and relationships as lines linking these boxes—often with additional symbols to signify the kind and cardiacality of the interactions—would be the visual representation of the ER model.
The relationships and entities within the hospital management system are shown in Fig. 1.1.

The patient, doctor, department, room, and appointment are the five main entities that are included. Patients may schedule many appointments, with a doctor and a single patient at each visit.Physicians are assigned to departments, and each department may have more than one physician on staff.Patients are assigned to rooms, and each room can accommodate several patients under a single doctor's care.The ER graphic also shows how a doctor is able to oversee many rooms.The entities are linked together by a number of links, including "has," "conducts," "assigned to," "employees," "houses," and "supervisedby," which illustrate the many relationships and interactions that exist in a medical setting.The diagram shows the relationships between the various components of the system and acts as a visual representation of the data model.

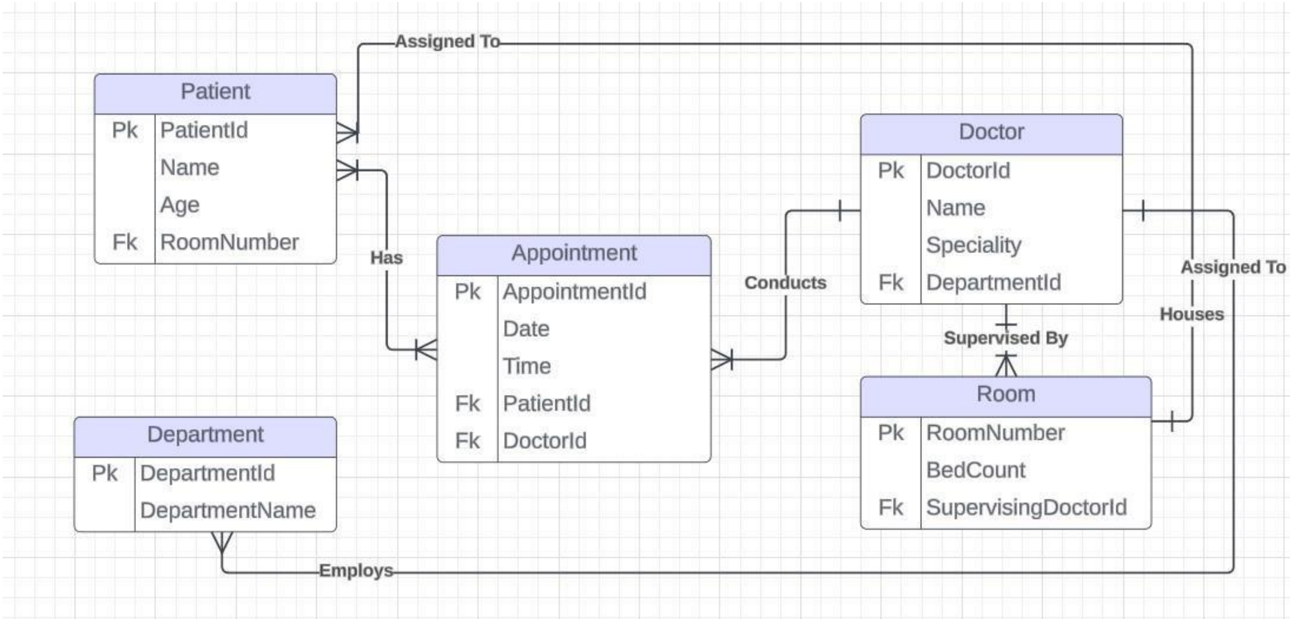

Fig.1.1:ERdiagramforHospitalManagementSystem

Que2CreatedatabasedesignforLibraryManagementSystemusingER Modelling

The following entities are included in the library management system: book, author, borrower, genre, and loan.The following is a relationship between these entities areas: A book is authored by one or more writers. • A writer can pen one or more books.

• A borrower may check out many books, but a book may be checked out by just one borrower. •in real time.
• A book falls into a specific genre.
• A genre can be connected to more than one book.
• The loan specifies when a book was checked out and when it must be returned.

These relationships led us to derive the subsequent ER model:

1. Entities
• Book with attributes: Title, ISBN, BookID, GenreID.
•Author with attributes: Name, BirthDate, and AuthorID.
• Borrower with properties: Name, Address, Phone, and Borrower ID.
• Genre with attributes (GenreName, GenreID).
• Loan with attributes: BookID, BorrowerID, Borrow Date, Due Date, Loan ID.
2. Relationships:
• A book is linked to its author(s) by means of a "writtenby" relationship.
One or more books are associated with an author via a "writes" relationship.

• A "borrows" relationship connects a borrower with books.
• A book and borrower have a relationship thanks to the "isborrowedby" connection.
• A book and a genre are connected by a "belongsto" relationship.
• Aloani is related to a borrower and a book through a "issued for" relationship. • A genre is connected to many books through a "encompasses" relationship.

To visualize the ER model, entities would be shown as boxes with relationships between them shown as lines or arrows. The types and cardinality of each link would be represented by annotations or symbols.

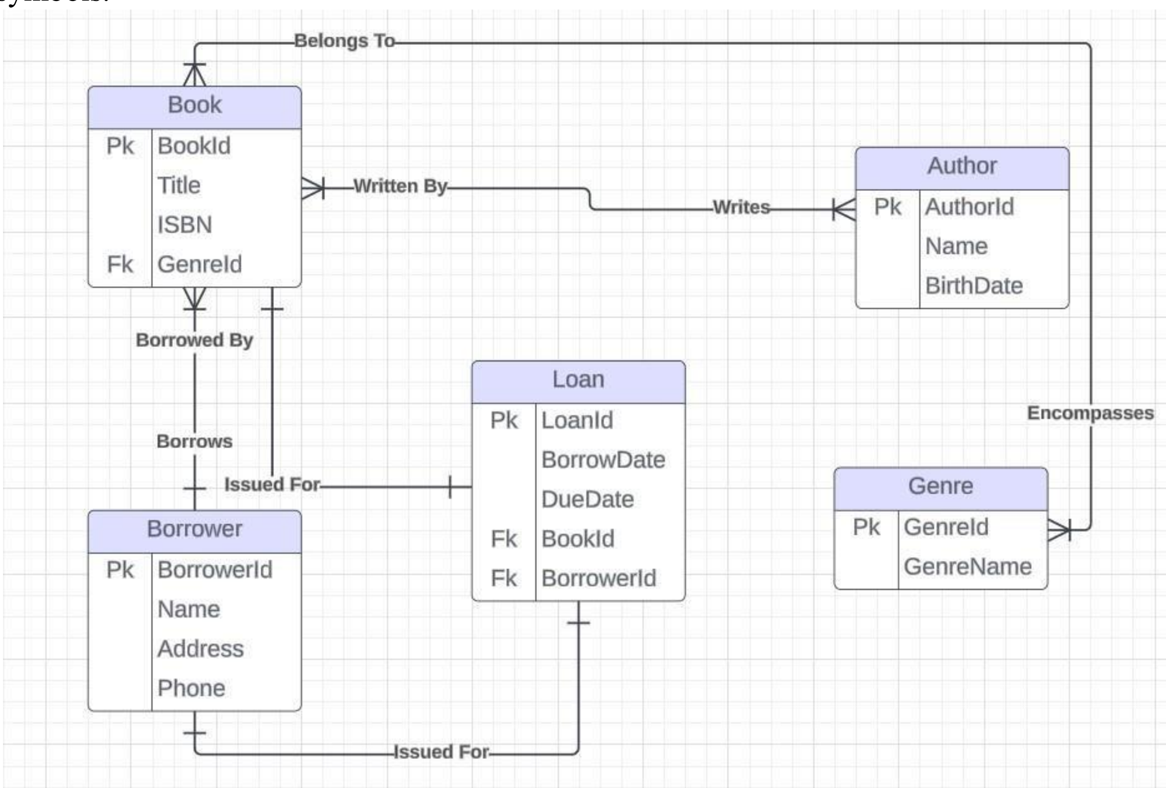

Fig.1.2:ERdiagramforLibraryManagementSystem

Figure 1.2 illustrates the connections and entities in the Library Management System.There are five main components to it: Book, Author, Borrower, Genre, and Loan.The graphic shows how a book is linked to one or more writers by a "written by" relationship, enabling numerous authors to contribute to a single work.Books are linked to authors by a "writes" relationship, meaning that an author is able to write more than one book.The relationship "borrows" links borrowers to books; this means that one borrower may check out numerous books at once, but only one borrower may check out a book at a time.Books are grouped by genres using a "belongsto" relationship, which indicates that a given book is part of a particular genre. Genres might include more than one book.The "issuedfor" relationships bind loans to both borrowers and books, indicating the date a book was borrowed and the return deadline.

PRACTICAL#5

Objective: Feature Selection and Variable Filtering.

Question#:

A) Select a dataset that has a minimum of 150 features.
B) Apply 3 Feature Selection Techniques
C) For each feature selection technique apply 3 machine learning models on it.
D) Compare the results.

TOOL USED: Weka
Feature Selection Technique->Gain Ratio->The gain ratio is a metric in decision trees that balances the information gain with the intrinsic information of attributes, helping to select the best attribute for splitting nodes.
No. of selelcted attribute-> 20

Algorithm: Naive Bayes->Probabilistic classification algorithm based on Bayes' theorem with an assumption of independence between features

```

Fig 5.2 Random Tree with 20 attributes

Algorithm:AdaBoost->It works by combining multiple weak learners (typically decision trees) to create a strong learner.t begins by assigning equal weights to all training samples. Then, it iteratively trains weak learners, focusing more on incorrectly classified samples in each iteration.The predictions of weak learners are combined through weighted voting, where more accurate learners have higher weights. This process continues until a predetermined number of iterations is reached or until perfect predictions are achieved

TOOL USED:- ORANGE

Orange is an open-source data visualization, analysis, and machine learning toolkit. It provides a user-friendly interface for data preprocessing, exploration, visualization, and predictive modeling.Orange offers a wide range of machine learning algorithms for classification, regression, clustering, and other tasks. Users can easily compare and evaluate different algorithms using built-in evaluation widgets.

KNN->K-Nearest Neighbors (KNN) is a simple yet effective supervised machine learning algorithm used for both classification and regression tasks. It's based on the idea that similar data points tend to belong to the same class or have similar values.When making predictions for a new data point, KNN calculates the distance between that point and all other points in the training dataset. Common distance metrics include

Euclidean distance, Manhattan distance, or cosine similarity.

PRACTICAL#6

Aim :- Perform Associative Mining In Weka and Orange on large datasets

Theory :- To perform association mining on large datasets, algorithms such as Apriori or FP-growth are employed. These algorithms efficiently extract frequent itemsets by iteratively identifying patterns within transactional data. With the support of these algorithms, associations between items can be discovered, aiding in tasks such as market basket analysis or recommendation systems. Efficient implementation and optimization are crucial for handling the computational complexity posed by large datasets, ensuring scalability and practical applicability in real-world scenarios.

PROCEDURE:

USING WEKA TOOL:

Scenario#1:WITH VALUE OF SUPPORT = 0.3 AND CONFIDENCE = 0.5

```
Apriori
=======

Minimum support: 0.45 (2082 instances)
Minimum metric <confidence>: 0.5
Number of cycles performed: 11

Generated sets of large itemsets:

Size of set of large itemsets L(1): 13

Size of set of large itemsets L(2): 7

Best rules found:

 1. biscuits=t 2605 ==> bread and cake=t 2083    conf:(0.8)
 2. milk-cream=t 2939 ==> bread and cake=t 2337    conf:(0.8)
 3. fruit=t 2962 ==> bread and cake=t 2325    conf:(0.78)
 4. baking needs=t 2795 ==> bread and cake=t 2191    conf:(0.78)
 5. frozen foods=t 2717 ==> bread and cake=t 2129    conf:(0.78)
 6. vegetables=t 2961 ==> bread and cake=t 2298    conf:(0.78)
 7. vegetables=t 2961 ==> fruit=t 2207    conf:(0.75)
 8. fruit=t 2962 ==> vegetables=t 2207    conf:(0.75)
 9. bread and cake=t 3330 ==> milk-cream=t 2337    conf:(0.7)
10. bread and cake=t 3330 ==> fruit=t 2325    conf:(0.7)
```

Fig 6.1 he rules found based on Support = 0.3 and Confidence = 0.5

The Apriori method, with a minimum support of 0.3 and a minimum confidence of 0.5 over 11 cycles, produced 2082 instances in Figure 6.1. Large itemset sets were produced by it; L(1) contained 13 sets, while L(2) contained 7. Among the notable rules are those describing associations, such biscuits leading to cake and bread or fruit leading to cake and bread.

Scenario#2:WITH VALUE OF SUPPORT = 0.5 AND CONFIDENCE = 0.7

```
Apriori
=======

Minimum support: 0.5 (2314 instances)
Minimum metric <confidence>: 0.7
Number of cycles performed: 10

Generated sets of large itemsets:

Size of set of large itemsets L(1): 10

Size of set of large itemsets L(2): 2

Best rules found:

 1. milk-cream=t 2939 ==> bread and cake=t 2337    conf:(0.8)
 2. fruit=t 2962 ==> bread and cake=t 2325    conf:(0.78)
 3. bread and cake=t 3330 ==> milk-cream=t 2337    conf:(0.7)
```

Fig 6.2 The rules found based on Support = 0.5 and Confidence = 0.7

The Apriori method, with a minimum support of 0.5 and a minimum confidence of 0.7 over 10 cycles, produced 2314 instances in Figure 6.2. Large itemset sets were produced by it. L(1) contained 10 sets, while L(2) contained 2.

Some Associations are milk-cream to bread and cake or fruit to bread and cake

Scenario#3:WITH VALUE OF SUPPORT = 0.3 AND CONFIDENCE = 0.7

```
=== Run information ===

Scheme:       weka.associations.Apriori -N 10 -T 0 -C 0.9 -D 0.05 -U 1.0 -M 0.7 -S -1.0 -c -1
Relation:     supermarket
Instances:    4627
Attributes:   217
[list of attributes omitted]
=== Associator model (full training set) ===

No large itemsets and rules found!
```

Fig 6.3 The rules found based on Support = 0.7 and Confidence = 0.9

In Figure 6.3, no rules were found in this iteration of the Apriori method, with a minimum support of 0.7 and a minimum confidence of 0.9 applied.This finding might be explained by the strict confidence and support standards that were established, which might have led to too few examples satisfying these requirements to create meaningful correlations. The lack of rules implies that there might not be frequent itemsets in the dataset that meet the designated confidence and support requirements.
